# Statistical Natural Language Processing Unsupervised machine learning

Çağrı Çöltekin

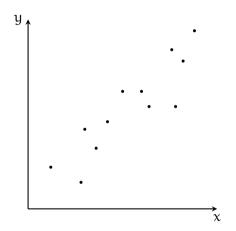

University of Tübingen Seminar für Sprachwissenschaft

Summer Semester 2020

## Supervised learning

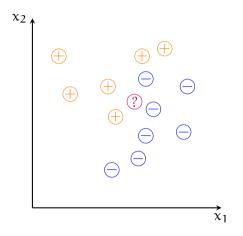

- The methods we studied so far are instances of supervised learning
- In supervised learning, we have a set of predictors x, and want to predict a response or outcome variable y
- During training, we have both input and output variables
- Training consist of estimating parameters w of a model
- ullet During prediction, we are given  $oldsymbol{x}$  and make predictions based on model we learned

#### Supervised learning: regression

- The response (outcome) variable
   (y) is a quantitative variable.
- Given the features (x) we want to predict the value of y

#### Supervised learning: classification

- The response (outcome) is a label. In the example: positive  $\bigcirc$  or negative  $\bigcirc$
- Given the features  $(x_1 \text{ and } x_2)$ , we want to predict the label of an unknown instance ?

# Supervised learning

how do we learn?

- The aim is to estimate a set of parameters *w*
- We define an *objective function*, and find the parameter values that minimize the objective
- The objective typically involves reducing the training error defined based on the true labels in the training data

# Unsupervised learning

- In unsupervised learning, we do not have labels in our training data
- Our aim is to find useful patterns/structure in the data
  - for exploratory study of the data
  - for augmenting / complementing supervised methods
- Close relationships with 'data mining', 'data science / analytics', 'knowledge discovery'
- Most unsupervised methods can be cast as graphical models with hidden variables
- Evaluation is difficult: we do not have 'true' labels/values

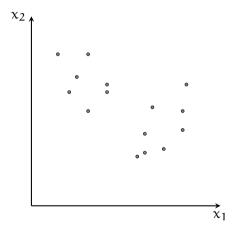

#### Today's lecture

- Clustering: find related groups of instances
- Density estimation: find a probability distribution that explains the data
- *Dimensionality reduction*: find an accurate/useful lower dimensional representation of the data
- Unsupervised learning in ANNs (RBMs, autoencoders)

#### Clustering: why do we do it?

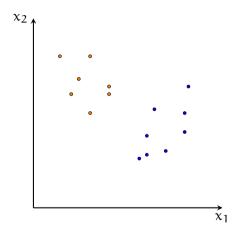

- The aim is to find groups of instances/items that are similar to each other
- Applications include
  - Clustering languages, dialects for determining their relations
  - Clustering (literary) texts, for e.g., authorship attribution
  - Clustering words for e.g., better parsing
  - Clustering documents, e.g., news into topics
  - ..

#### Clustering in two dimensional space

• Unlike classification, we do not have labels

## Clustering in two dimensional space

- Unlike classification, we do not have labels
- We want to find 'natural' groups in the data
- Intuitively, similar or closer data points are grouped together

#### Similarity and distance

- The notion of distance (similarity) is important in clustering. A distance measure D,
  - is symmetric: D(a, b) = D(b, a)
  - non-negative:  $D(a, b) \ge 0$ 
    - for all a, b, and it D(a, b) = 0 iff a = b
  - obeys triangle inequality:  $D(a, b) + D(b, c) \ge D(a, c)$
- The choice of distance is application specific
- We will often face with defining distance measures between linguistic units (letters, words, sentences, documents, ...)

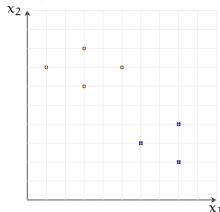

# Distance measures in Euclidean space

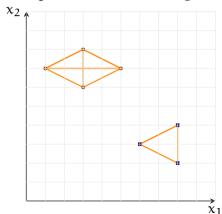

• Euclidean distance:

$$\|\mathbf{a} - \mathbf{b}\| = \sqrt{\sum_{j=1}^{k} (a_j - b_j)^2}$$

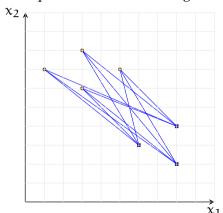

Manhattan distance:

$$\|\mathbf{a} - \mathbf{b}\|_1 = \sum_{j=1}^k |a_j - b_j|$$

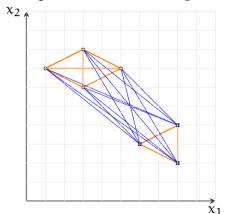

$$\sum_{k=1}^K \sum_{\alpha \in C_k} \sum_{b \in C_k} d(\alpha, b)$$

$$\sum_{k=1}^{K} \sum_{\alpha \in C_k} \sum_{b \in C_k} d(\alpha, b)$$
$$\sum_{k=1}^{K} \sum_{\alpha \in C_k} \sum_{b \notin C_k} d(\alpha, b)$$

$$\sum_{k=1}^{K} \sum_{\alpha \in C_k} \sum_{b \in C_k} d(\alpha, b)$$
$$\sum_{k=1}^{K} \sum_{\alpha \in C_k} \sum_{b \notin C_k} d(\alpha, b)$$

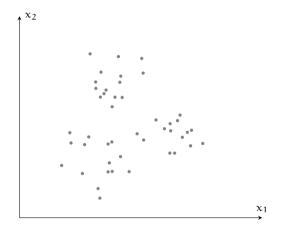

## K-means algorithm

K-means is a popular method for clustering.

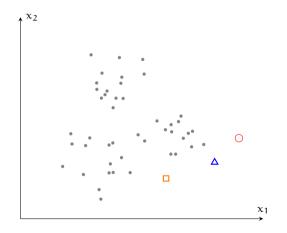

- 1. Randomly choose *centroids*,  $m_1, \ldots, m_K$ , representing K clusters
- 2. Repeat until convergence
  - Assign each data point to the cluster of the nearest centroid
  - Re-calculate the centroid locations based on the assignments

Effectively, we are finding a *local minimum* of the sum of squared Euclidean distance within each cluster

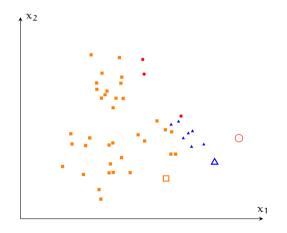

$$\frac{1}{2} \sum_{k=1}^{K} \sum_{a \in C_k} \sum_{b \in C_k} \|a - b\|^2$$

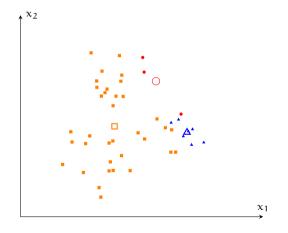

- The data
- Set cluster centroids randomly
- Assign data points to the closest centroid
- Recalculate the centroids

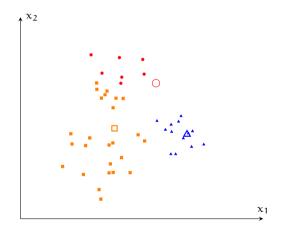

- The data
- Set cluster centroids randomly
- Assign data points to the closest centroid
- Recalculate the centroids

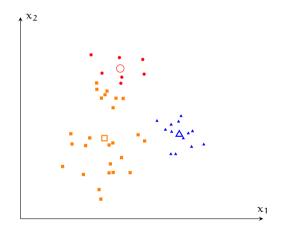

- The data
- Set cluster centroids randomly
- Assign data points to the closest centroid
- Recalculate the centroids

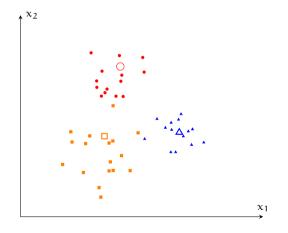

- The data
- Set cluster centroids randomly
- Assign data points to the closest centroid
- Recalculate the centroids

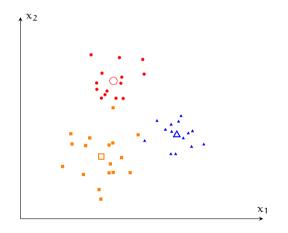

- The data
- Set cluster centroids randomly
- Assign data points to the closest centroid
- Recalculate the centroids

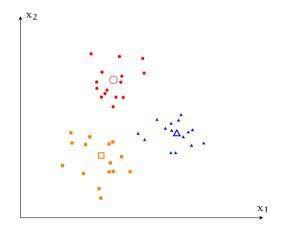

- The data
- Set cluster centroids randomly
- Assign data points to the closest centroid
- Recalculate the centroids

- The data
- Set cluster centroids randomly
- Assign data points to the closest centroid
- Recalculate the centroids

- The data
- Set cluster centroids randomly
- Assign data points to the closest centroid
- Recalculate the centroids

- The data
- Set cluster centroids randomly
- Assign data points to the closest centroid
- Recalculate the centroids

#### K-means: some issues

- K-means requires the data to be in an Euclidean space
- K-means is sensitive to outliers
- The results are sensitive to initialization
  - There are some smarter ways to select initial points
  - One can do multiple initializations, and pick the best (with lowest within-group squares)
- It works well with approximately equal-size round-shaped clusters
- We need to specify number of clusters in advance

#### How many clusters?

- The number of clusters is defined for some problems, e.g., classifying news into a fixed set of topics/interests
- For others, there is no clear way to select the best number of clusters
- The error (within cluster scatter) decreases with increasing number of clusters, using a test set or cross validation is not useful either
- A common approach is clustering for multiple K values, and picking where there is an 'elbow' in the graph of the error function

#### How many clusters?

This plot is sometimes called a *scree plot*.

#### K-medoids

- K-medoids algorithm is an alternation of K-means
- Instead of calculating centroids, we try to find most typical data point (medoids) at each iteration
- K-medoids can work with distances, does not need feature vectors to be in an Euclidean space
- It is less sensitive to outliers
- It is computationally more expensive than K-means

# Hierarchical clustering

- Instead of a flat division to clusters as in K-means, hierarchical clustering builds a hierarchy based on similarity of the data points
- There are two main 'modes of operation':

Bottom-up or agglomerative clustering

- starts with individual data points,
- merges the clusters until all data is in a single cluster

Top-down or *divisive* clustering

- starts with a single cluster,
- and splits until all leaves are single data points

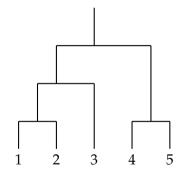

# Hierarchical clustering

- Hierarchical clustering operates on distances (or similarities)
- The result is a binary tree called *dendrogram*
- Dendrograms are easy to interpret (especially if data is hierarchical)
- The algorithm does not commit to the number of clusters K from the start, the dendrogram can be 'cut' at any height for determining the clusters

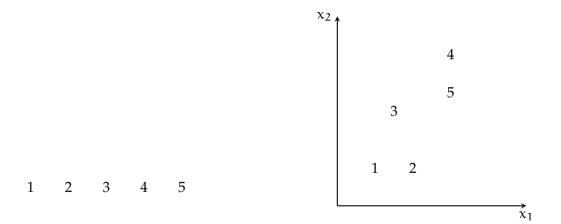

19 / 48

# Agglomerative clustering

- Compute the similarity/distance matrix
- 2. Assign each data point to its own cluster
- 3. Repeat until no clusters left to merge
  - Pick two clusters that are most similar to each other
  - Merge them into a single cluster

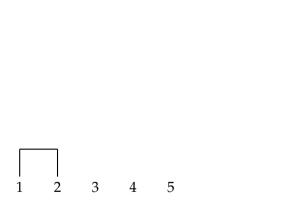

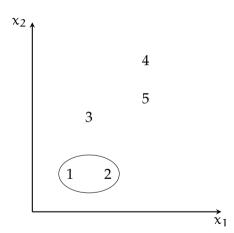

## Agglomerative clustering demonstration

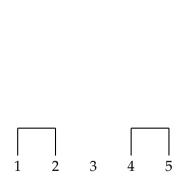

Ç. Çöltekin, SfS / University of Tübingen

Average mean inter-cluster distance
Centroid distance between the
centroids

Note: we only need distances, (feature) vectors are not necessary

## Clustering evaluation

#### Evaluating clustering results is often non-trivial

- Internal evaluation is based a metric that aims to indicate 'good clustering': e.g., *Dunn index, gap statistic, silhouette*
- External metrics can be useful if we have labeled *test* data: e.g., *V-measure*,  $B^3ed$  *F-score*
- The results can be tested on the target application: e.g., word-clusters evaluated based on their effect on parsing accuracy
- Human judgments, manual evaluation 'looks good to me'

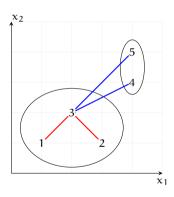

### Clustering evaluation

internal metric example: silhouette

$$s_{i} = \frac{b(i) - a(i)}{\max(a(i), b(i))}$$

where

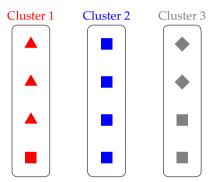

- a(i) average distance between object i and and objects in the same cluster
- b(i) average distance between object i and and objects in the *closest* cluster

### Clustering evaluation

external metrics: general intution

- We want clusters that contain members of a single gold-standard class (homogeniety)
- We want all members of a class to be in a single cluster (completeness)

Note the similarity with precision and recall.

## Clustering: some closing notes

- We do not have proper evaluation procedures for clustering results (for unsupervised learning in general)
- Some clustering methods are unstable, slight changes in the data or parameter choices may change the results drastically
- Approaches against instability include some validation methods, or producing 'probabilistic' dendrograms by running clustering with different options

### Density estimation

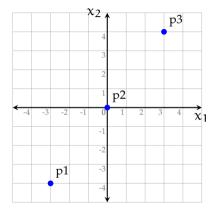

- K-means treats all data points in a cluster equally
- A 'soft' version of K-means is density estimation for Gaussian mixtures, where
  - We assume the data comes from a mixture of K Gaussian distributions
  - We try to find the parameters of each distribution (instead of centroids) that maximizes the likelihood of the data
- Unlike K-means, mixture of Gaussians assigns probabilities for each data point belonging to one of the clusters
- It is typically estimated using the expectation-maximization (EM) algorithm

## Density estimation using the EM algorithm

- The EM algorithm (or its variations) is used in learning models with latent/hidden variables
- It is closely related to the K-means algorithm
- 1. Initialize the parameters (e.g., randomly) of K multivariate normal distributions  $(\mu, \Sigma)$
- 2. Iterate until convergence:
- E-step Given the parameters, compute the membership 'weights', the probability of each data point belonging to each distribution
- M-step Re-estimate the mixture density parameters using the calculated membership weights in the E-step

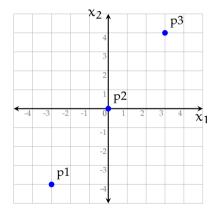

## Principal component Analysis

- Principal component analysis (PCA) is a method of dimensionality reduction
- PCA maps the original data into a lower dimensional space by a linear transformation (rotation)
- The transformed lower-dimensional variables retain most of the variation (=information) in the input
- PCA can be used for
  - visualization
  - data compression
  - reducing dimensionality of features for other machine learning methods
  - eliminating noise

#### Questions:

- How many dimensions do we have?
- How many dimensions do we need?

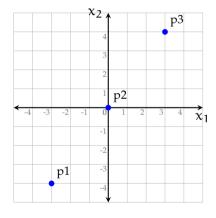

#### Questions:

- How many dimensions do we have?
- How many dimensions do we need?
- Short divergence: calculate the covariance matrix

$$\Sigma = \begin{bmatrix} ? & ? \\ ? & ? \end{bmatrix}$$

- What is the correlation between  $x_1$  and  $x_2$ ?

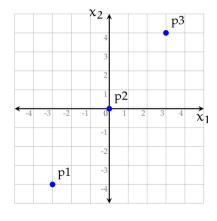

#### Questions:

- How many dimensions do we have?
- How many dimensions do we need?
- Short divergence: calculate the covariance matrix

$$\Sigma = \begin{bmatrix} \sigma_{x_1}^2 & \sigma_{x_2, x_1} \\ \sigma_{x_1, x_2} & \sigma_{x_2}^2 \end{bmatrix}$$

- What is the correlation between  $x_1$  and  $x_2$ ?

#### Questions:

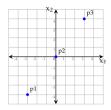

- How many dimensions do we have?
- How many dimensions do we need?
- Short divergence: calculate the covariance matrix

$$\Sigma = \begin{bmatrix} \frac{18}{3} & 8\\ 8 & \frac{32}{3} \end{bmatrix}$$

- What is the correlation between  $x_1$  and  $x_2$ ?

What if we reduce the data to:

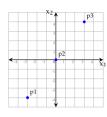

What if we reduce the data to:

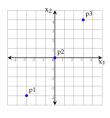

Going back to the original coordinates is easy, rotate using:

$$A = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} = \begin{bmatrix} \frac{3}{5} & -\frac{4}{5} \\ \frac{4}{5} & \frac{3}{5} \end{bmatrix}$$

What if we reduce the data to:

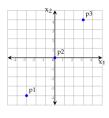

Going back to the original coordinates is easy, rotate using:

$$A = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} = \begin{bmatrix} \frac{3}{5} & -\frac{4}{5} \\ \frac{4}{5} & \frac{3}{5} \end{bmatrix}$$

$$\mathfrak{p}1 = A \times \begin{bmatrix} -5 \\ 0 \end{bmatrix} = \begin{bmatrix} -3 \\ -4 \end{bmatrix} \quad \mathfrak{p}1 = A \times \begin{bmatrix} 0 \\ 0 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \mathfrak{p}1 = A \times \begin{bmatrix} 5 \\ 0 \end{bmatrix} = \begin{bmatrix} 3 \\ 4 \end{bmatrix}$$

What if we reduce the data to:

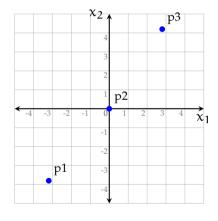

Going back to the original coordinates is easy, rotate using:

$$A = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} = \begin{bmatrix} \frac{3}{5} & -\frac{4}{5} \\ \frac{4}{5} & \frac{3}{5} \end{bmatrix}$$

$$p1 = A \times \begin{bmatrix} -5 \\ 0 \end{bmatrix} = \begin{bmatrix} -3 \\ -4 \end{bmatrix}$$
  $p1 = A \times \begin{bmatrix} 0 \\ 0 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$   $p1 = A \times \begin{bmatrix} 5 \\ 0 \end{bmatrix} = \begin{bmatrix} 3 \\ 4 \end{bmatrix}$ 

We can recover the original points perfectly. In this example the inherent dimensionality of the data is only 1.

- What if the variables were not perfectly but strongly correlated?
- We could still do a similar transformation:

 Discarding z<sub>2</sub> results in a small reconstruction error:

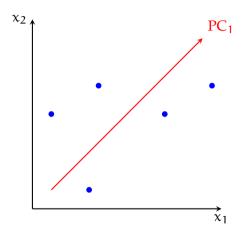

$$p1 = A \times \begin{bmatrix} -5 \\ 0 \end{bmatrix} = \begin{bmatrix} -3 \\ -4 \end{bmatrix}$$

• Note:  $z_1$  (also  $z_2$ ) is a linear combination of original variables

## Why do we want to reduce the dimensionality

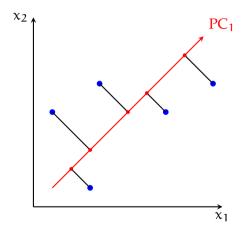

- Visualizing high-dimensional data becomes possible
- If we use the data for other ML methods,
  - we reduce the computation time
  - we may avoid 'the curse of dimensionality'
- Decorrelation is useful in some applications
- We compress the data (in a lossy way)
- We eliminate noise (assuming a high signal to noise ratio)

#### Different views on PCA

• Find the direction of the largest variance

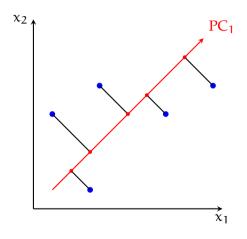

#### Different views on PCA

- Find the direction of the largest variance
- Find the projection with the least reconstruction error

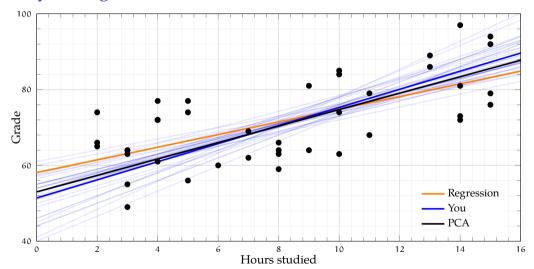

34 / 48

#### Different views on PCA

- Find the direction of the largest variance
- Find the projection with the least reconstruction error
- Find a lower dimensional latent Gaussian variable such that the observed variable is a mapping of the latent variable to a higher dimensional space (with added noise)

## Aside: your regression estimates and PCA

#### How to find PCs

- When viewed as *maximizing variance* or *reducing the reconstruction error*, we can write the appropriate objective function and find the vectors that minimize it
- In latent variable interpretation, we can use EM as in estimating mixtures of Gaussians
- The principal components are the eigenvectors of the correlation matrix, where large eigenvalues correspond to components with large variation
- A numerically stable way to obtain principal components is doing *singular* value decomposition (SVD) on the input data

## PCA as matrix factorization (eigenvalue decomposition)

• One can compute PCA by decomposing the covariance matrix as (note  $\Sigma = X^T X$ )

$$\Sigma = U \Lambda U^{\mathsf{T}}$$

- the columns of **U** are the principal components (eigenvectors)
- $\Lambda$  is a diagonal matrix of eigenvalues
- Another option is SVD, which factorizes the input vector (k variables × n data points) as

$$X = UDV^*$$

- $\mathbf{U}$  (k × k) contains the eigenvectors as before,
- **D** (k × n) diagonal matrix  $D^2 = \Lambda$
- $V^*$  is a n × n unitary matrix

<sup>\*</sup> The above is correct for centered variables, otherwise the formulas get slightly more complicated.

### Some practical notes on PCA

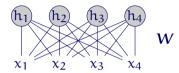

- Variables need to be centered
- Scales of the variables matter, standardizing may be a good idea depending on the units/scales of the individual variables
- The sign/direction of the principal component (vector) is not important
- If there are more variables than the data points, we can still calculate the principal components, but there will be at most n-1 PCs
- PCA will be successful if variables are correlated, there are extensions for dealing with nonlinearities (e.g., kernel PCA, ICA, t-SNE)

38 / 48

## Unsupervised learning in ANNs

- Restricted Boltzmann machines (RBM) similar to the latent variable models (e.g., Gaussian mixtures), consider the representation learned by hidden layers as hidden variables ( $\mathbf{h}$ ), and learn  $\mathbf{p}(\mathbf{x}, \mathbf{h})$  that maximize the probability of the (unlabeled)data
- Autoencoders train a constrained feed-forward network to predict its output

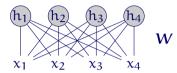

### Restricted Boltzmann machines (RBMs)

- RBMs are unsupervised latent variable models, they learn only from unlabeled data
- They are generative models of the joint probability p(h, x)
- They correspond to undirected graphical models
- No links within layers
- The aim is to learn useful features (h)

<sup>\*</sup>Biases are omitted in the diagrams and the formulas for simplicity.

### Restricted Boltzmann machines (RBMs)

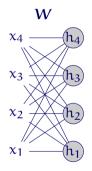

- RBMs are unsupervised latent variable models, they learn only from unlabeled data
- They are generative models of the joint probability p(h, x)
- They correspond to undirected graphical models
- No links within layers
- The aim is to learn useful features (h)

<sup>\*</sup>Biases are omitted in the diagrams and the formulas for simplicity.

### The distribution defined by RBMs

$$p(\mathbf{h}, \mathbf{x}) = \frac{e^{\mathbf{h}^{\mathsf{T}} \mathbf{W} \mathbf{x}}}{\mathsf{Z}}$$

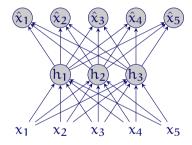

This calculation is intractable (Z is difficult to calculate). But conditional distributions are easy to calculate

$$p(\mathbf{h}|\mathbf{x}) = \prod_{j} p(\mathbf{h}_{j}|\mathbf{x}) = \frac{1}{1 + e^{\mathbf{W}_{j}\mathbf{x}}}$$
$$p(\mathbf{x}|\mathbf{h}) = \prod_{j} p(\mathbf{x}_{k}|\mathbf{h}) = \frac{1}{1 + e^{\mathbf{W}_{k}^{\mathsf{T}}\mathbf{h}}}$$

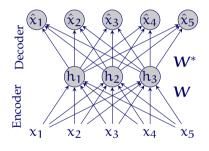

## Learning in RBMs

- We want to maximize the probability the model assigns to the input, p(x), or equivalently minimize  $-\log p(x)$
- In general, this is computationally expensive
- *Contrastive divergence algorithm* is a well known algorithm that efficiently finds an approximate solution

#### Autoencoders

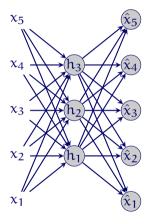

#### Autoencoders

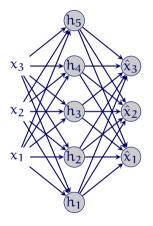

- Autoencoders are standard feed-forward networks
- The main difference is that they are trained to predict their input (they try to learn the identity function)
- The aim is to learn useful representations of input at the hidden layer
- The weights are often shared/tied (W\* = W<sup>T</sup>)

## Under-complete autoencoders

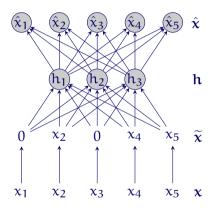

- An autoencoder is said to be under-complete if there are fewer hidden units than inputs
- The network is forced to learn a compact representation of the input (compress)
- An autoencoder with a single hidden layer approximates the PCA
- We need multiple layers for learning non-linear features

## Over-complete autoencoders

- An autoencoder is said to be over-complete if there are more hidden units than inputs
- The network can normally memorize the input perfectly
- This type of networks are useful if trained with a regularization term resulting in sparse hidden units (e.g., L1 regularization)

### Denoising autoencoders

- Instead of providing the exact input, we introduce noise by
  - randomly setting some inputs to 0 (dropout)
  - adding random (Gaussian) noise
- Network is still expected to reconstruct the original input (without noise)

## Unsupervised pre-training

- A common use case for RBMs and autoencoders are as pre-training methods for supervised networks
- Autoencoders or RBMs are trained using unlabeled data
- The weights learned during the unsupervised learning is used for initializing the weights of a supervised network
- This approach has been one of the reasons for success of deep networks

### Summary

- In unsupervised learning, we do not have labels. Our aim is to find/exploit (latent) structure in the data
- Unsupervised methods try to discover 'hidden' structure in the data
   Clustering finds groups in the data
   Density estimation estimates parameters of latent probability distributions
   Dimensionality reduction transforms the data in a low dimensional space
   while keeping most of the information in the original data

## Summary

- In unsupervised learning, we do not have labels. Our aim is to find/exploit (latent) structure in the data
- Unsupervised methods try to discover 'hidden' structure in the data
   Clustering finds groups in the data
   Density estimation estimates parameters of latent probability distributions
   Dimensionality reduction transforms the data in a low dimensional space
   while keeping most of the information in the original data

#### After the break:

- More ML: sequence learning
- Common CL tasks: tokenization, morphology, syntactic parsing, (lexical) semantics,
- Some NLP applications: text classification, and maybe more

## Derivation of PCA by maximizing the variance

- We focus on the first PC  $(z_1)$ , which maximizes the variance of the data onto itself
- We are interested only on the direction, so we choose  $z_1$  to be a unit vector  $(\|z_1\| = 1)$
- Remember that to project a vector onto another, we simply use dot product, So the projected data points are  $zx_i$  for i = 1, ..., N.
- The variance of the projected data points (that we want to maximize) is,

$$\sigma_{z_1} = \frac{1}{N} \sum_{i}^{N} (z_1 x_i - z_1 \bar{x}_i)^2 = z_1^{\mathsf{T}} \Sigma z_1$$

where  $\Sigma_x$  is the covariance matrix of the unprojected data

## Derivation of PCA by maximizing the variance (cont.)

• The problem becomes maximize

$$z_1^\mathsf{T} \Sigma z$$

with the constraint  $||z_1|| = z_1^\mathsf{T} z_1 = 1$ 

 Turning it into a unconstrained optimization problem with Lagrange multipliers, we minimize

$$z_1^\mathsf{T} \Sigma z + \lambda_1 (1 - z_1^\mathsf{T} z_1)$$

Taking the derivative and setting it to 0 gives us

$$\Sigma z_1 = \lambda_1 z_1$$

Note: by definition,  $z_1$  is an eigenvector of  $\Sigma$ , and  $\lambda_1$  is the corresponding eigenvalue

•  $z_1$  is the first principal component, we can now compute the second principal component with the constraint that it has to be orthogonal to the first one
