Summer Semester 2020

Supervised learning: regression

- The response (outcome) variable (y) is a quantitative variable.
- Given the features (x) we want to predict the value

Ç. Çöltekin, SfS / University of Tübingen

Supervised learning

how do we learn?

ullet The aim is to estimate a set of parameters $oldsymbol{w}$

Recap Clustering Density estimation PCA Autoencoders

- We define an objective function, and find the parameter values that minimize the objective
- The objective typically involves reducing the training error defined based on the true labels in the training data

Recap Clustering Density estimation PCA Autoencoders

Today's lecture

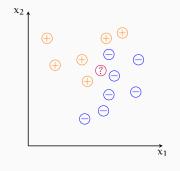

- Clustering: find related groups of instances
- Density estimation: find a probability distribution that explains the data
- Dimensionality reduction: find an accurate/useful lower dimensional representation of the data
- Unsupervised learning in ANNs (RBMs, autoencoders)

Supervised learning

- The methods we studied so far are instances of supervised
- In supervised learning, we have a set of predictors x, and want to predict a response or outcome variable \boldsymbol{y}
- During training, we have both input and output variables
- Training consist of estimating parameters w of a model
- During prediction, we are given x and make predictions based on model we learned

Recap Clustering Density estimation PCA Autoencoders

Supervised learning: classification

- The response (outcome) is a label. In the example: positive or negative
- Given the features (x_1) and x_2), we want to predict the label of an unknown instance ?

Ç. Çöltekin, SfS / University of Tübinger

Recap Clustering Density estimation PCA Autoencoders

Unsupervised learning

- In unsupervised learning, we do not have labels in our training data
- Our aim is to find useful patterns/structure in the data
 - for exploratory study of the data
 - for augmenting / complementing supervised methods
- Close relationships with 'data mining', 'data science / analytics', 'knowledge discovery'
- Most unsupervised methods can be cast as graphical models with hidden variables
- Evaluation is difficult: we do not have 'true' labels/values

Ç. Çöltekin, SfS / University of Tübingen

Recap Clustering Density estimation PCA Autoencoders

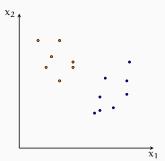

Clustering: why do we do it?

- The aim is to find groups of instances/items that are similar to each other
- Applications include
 - Clustering languages, dialects for determining their
 - Clustering (literary) texts, for e.g., authorship attribution
 - Clustering words for e.g., better parsing
 - Clustering documents, e.g., news into topics

C. Cöltekin, SfS / University of Tübingen Summer Semester 2020 6 / 48 C. Cöltekin, SfS / University of Tübingen Summer Semester 2020

Clustering in two dimensional space

Recap Clustering Density estimation PCA Autoencoders

- Unlike classification, we do not have labels
- We want to find 'natural' groups in the data
- Intuitively, similar or closer data points are grouped together

Recap Clustering Density estimation PCA Autoencoders

Distance measures in Euclidean space

• Euclidean distance:

$$\|a-b\|=\sqrt{\sum_{j=1}^k(a_j-b_j)^2}$$

• Manhattan distance:

$$\|\mathbf{a} - \mathbf{b}\|_1 = \sum_{j=1}^k |a_j - b_j|$$

Recap Clustering Density estimation PCA Autoencoders

1. Randomly choose $\textit{centroids}, \, m_1, \dots, m_K, \, representing \, K$

Re-calculate the centroid locations based on the

 $\frac{1}{2}\sum_{k=1}^{K}\sum_{a\in C}\sum_{b\in C}\|a-b\|^{2}$

Effectively, we are finding a local minimum of the sum of

squared Euclidean distance within each cluster

- Assign each data point to the cluster of the nearest centroid

K-means is a popular method for clustering.

Ç. Çöltekin, SfS / University of Tübinger

C. Cöltekin, SfS / University of Tübingen

• We will often face with defining distance measures between linguistic units (letters, words, sentences, documents,...)

for all a, b, and it D(a, b) = 0 iff a = b

• The choice of distance is application specific

Recap Clustering Density estimation PCA Autoencoders

 $\bullet\,$ The notion of distance (similarity) is important in

– obeys triangle inequality: $D(a,b) + D(b,c) \geqslant D(a,c)$

clustering. A distance measure D,

non-negative: $D(a, b) \ge 0$

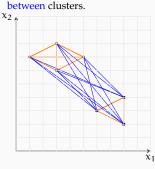

- is symmetric: D(a, b) = D(b, a)

Similarity and distance

How to do clustering

Most clustering algorithms try to minimize the scatter within each cluster. Which is equivalent to maximizing the scatter

Recap Clustering Density estimation PCA Autoencoders

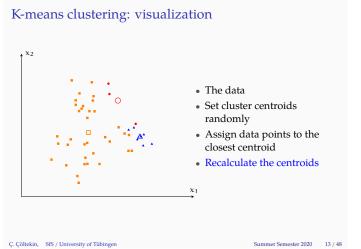

$$\sum_{k=1}^{K} \sum_{\alpha \in C_k} \sum_{b \notin C_k} d(\alpha, b)$$

Recap Clustering Density estimation PCA Autoencoders

K-means: some issues

- K-means requires the data to be in an Euclidean space
- K-means is sensitive to outliers
- The results are sensitive to initialization

 - There are some smarter ways to select initial pointsOne can do multiple initializations, and pick the best (with lowest within-group squares)
- It works well with approximately equal-size round-shaped clusters
- We need to specify number of clusters in advance

K-means clustering: visualization

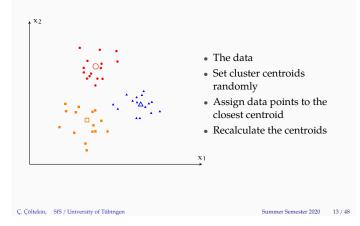

Recap Clustering Density estimation PCA Autoencoders

Recap Clustering Density estimation PCA Autoencoders

K-means clustering: visualization

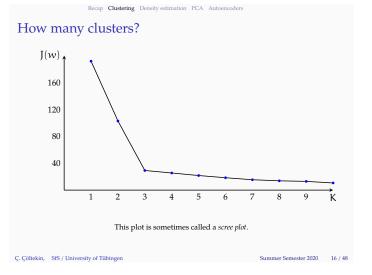

Recap Clustering Density estimation PCA Autoencoders

How many clusters?

- The number of clusters is defined for some problems, e.g., classifying news into a fixed set of topics/interests
- $\bullet\,$ For others, there is no clear way to select the best number of clusters
- The error (within cluster scatter) decreases with increasing number of clusters, using a test set or cross validation is not useful either
- A common approach is clustering for multiple K values, and picking where there is an 'elbow' in the graph of the error function

Ç. Çöltekin, SfS / University of Tübingen C. Cöltekin, SfS / University of Tübingen

Recap Clustering Density estimation PCA Autoencoders

Hierarchical clustering

- · Instead of a flat division to clusters as in K-means, hierarchical clustering builds a hierarchy based on similarity of the data points
- There are two main 'modes of operation':

Bottom-up or agglomerative clustering

- starts with individual data points,
- merges the clusters until all data is in a single cluster

Top-down or divisive clustering

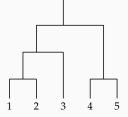

- · starts with a single cluster,
- · and splits until all leaves are single data points

Ç. Çöltekin, SfS / University of Tübinge

Recap Clustering Density estimation PCA Autoencoders

Agglomerative clustering

- 1. Compute the similarity/distance matrix
- 2. Assign each data point to its own cluster
- 3. Repeat until no clusters left to merge
 - Pick two clusters that are most similar to each other
 - Merge them into a single cluster

Ç. Çöltekin, SfS / University of Tübingen

distance

Centroid distance between the centroids

K-medoids

• K-medoids algorithm is an alternation of K-means

cap Clustering Density estimation PCA Autoencoders

- Instead of calculating centroids, we try to find most typical data point (medoids) at each iteration
- K-medoids can work with distances, does not need feature vectors to be in an Euclidean space
- It is less sensitive to outliers
- It is computationally more expensive than K-means

Recap Clustering Density estimation PCA Autoencoders

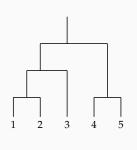

Hierarchical clustering

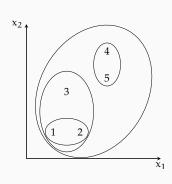

- · Hierarchical clustering operates on distances (or similarities)
- The result is a binary tree called dendrogram
- Dendrograms are easy to interpret (especially if data is hierarchical)
- The algorithm does not commit to the number of clusters K from the start, the dendrogram can be 'cut' at any height for determining the clusters

Recap Clustering Density estimation PCA Autoencoders

Clustering evaluation

Evaluating clustering results is often non-trivial

- Internal evaluation is based a metric that aims to indicate 'good clustering': e.g., Dunn index, gap statistic, silhouette
- External metrics can be useful if we have labeled test data: e.g., V-measure, B³ed F-score
- · The results can be tested on the target application: e.g., word-clusters evaluated based on their effect on parsing
- Human judgments, manual evaluation 'looks good to me'

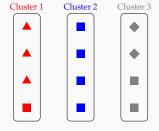

Ç. Çöltekin, SfS / University of Tübingen

Recap Clustering Density estimation PCA Autoencoders

Clustering evaluation

external metrics: general intution

- · We want clusters that contain members of a single gold-standard class (homogeniety)
- We want all members of a class to be in a single cluster (completeness)

Note the similarity with precision and recall.

Ç. Çöltekin, SfS / University of Tübingen

Recap Clustering Density estimation PCA Autoencoders

Density estimation

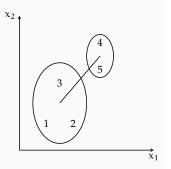

- K-means treats all data points in a cluster equally
- A 'soft' version of K-means is density estimation for Gaussian mixtures, where
 - We assume the data comes from a mixture of K Gaussian distributions
 - We try to find the parameters of each distribution (instead of centroids) that maximizes the likelihood of the data
- Unlike K-means, mixture of Gaussians assigns probabilities for each data point belonging to one of the clusters
- It is typically estimated using the expectation-maximization (EM) algorithm

How to calculate between cluster distances

Clustering evaluation

internal metric example: silhouette

$$s_{i} = \frac{b(i) - a(i)}{\max(a(i), b(i))}$$

where

- a(i) average distance between object i and and objects in the same
- b(i) average distance between object i and and objects in the ${\it closest}$ cluster

Ç. Çöltekin, SfS / University of Tübinger

Recap Clustering Density estimation PCA Autoencoders

Clustering: some closing notes

- · We do not have proper evaluation procedures for clustering results (for unsupervised learning in general)
- Some clustering methods are unstable, slight changes in the data or parameter choices may change the results drastically
- Approaches against instability include some validation methods, or producing 'probabilistic' dendrograms by running clustering with different options

Ç. Çöltekin, SfS / University of Tübingen

Recap Clustering Density estimation PCA Autoencoders

Density estimation using the EM algorithm

- The EM algorithm (or its variations) is used in learning models with latent/hidden variables
- It is closely related to the K-means algorithm
- $1. \ \ Initialize \ the \ parameters \ (e.g., randomly) \ of \ K \ multivariate$ normal distributions (μ, Σ)
- 2. Iterate until convergence:

E-step Given the parameters, compute the membership 'weights', the probability of each data point belonging to each distribution

M-step Re-estimate the mixture density parameters using the calculated membership weights in the E-step

Ç. Çöltekin, SfS / University of Tübingen C. Cöltekin. SfS / University of Tübingen

Principal component Analysis

- · Principal component analysis (PCA) is a method of dimensionality reduction
- PCA maps the original data into a lower dimensional space by a linear transformation (rotation)
- The transformed lower-dimensional variables retain most of the variation (=information) in the input
- PCA can be used for
 - visualization
 - visualization
 data compression
 - reducing dimensionality of features for other machine learning methods

Recap Clustering Density estimation PCA Autoencoders

Going back to the original coordinates is easy, rotate using:

 $A = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} = \begin{bmatrix} \frac{3}{5} & -\frac{4}{5} \\ \frac{4}{5} & \frac{3}{5} \end{bmatrix}$

 $\mathfrak{p}1=A\times\begin{bmatrix}-5\\0\end{bmatrix}=\begin{bmatrix}-3\\-4\end{bmatrix}\quad\mathfrak{p}1=A\times\begin{bmatrix}0\\0\end{bmatrix}=\begin{bmatrix}0\\0\end{bmatrix}\mathfrak{p}1=A\times\begin{bmatrix}5\\0\end{bmatrix}=\begin{bmatrix}3\\4\end{bmatrix}$

We can recover the original points perfectly. In this example the

eliminating noise

Ç. Çöltekin, SfS / University of Tübingen

PCA: A toy example (2)

What if we reduce the data to:

Ouestions:

- How many dimensions do we have?
- How many dimensions do we need?
- Short divergence: calculate the covariance matrix

$$\Sigma = \begin{bmatrix} \frac{18}{3} & 8\\ 8 & \frac{32}{3} \end{bmatrix}$$

 What is the correlation between x_1 and x_2 ?

C. Cöltekin, SfS / University of Tübingen

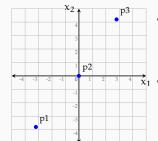

PCA: a toy example

p1

Recap Clustering Density estimation PCA Autoencoders

Recap Clustering Density estimation PCA Autoencoders

PCA: A toy example (3)

- What if the variables were not perfectly but strongly correlated?
- We could still do a similar transformation:

• Discarding z_2 results in a small reconstruction error:

$$\mathfrak{p1} = A \times \begin{bmatrix} -5 \\ 0 \end{bmatrix} = \begin{bmatrix} -3 \\ -4 \end{bmatrix}$$

 Note: z₁ (also z₂) is a linear combination of original variables

Different views on PCA

Summer Semester 2020 32 / 48

Recap Clustering Density estimation PCA Autoencoders

Why do we want to reduce the dimensionality

inherent dimensionality of the data is only 1.

- · Visualizing high-dimensional data becomes possible
- If we use the data for other ML methods,
 - we reduce the computation time
 - we may avoid 'the curse of dimensionality'
- Decorrelation is useful in some applications
- We compress the data (in a lossy way)
- We eliminate noise (assuming a high signal to noise ratio)

Ç. Çöltekin, SfS / University of Tübingen

Ç. Çöltekin, SfS / University of Tübingen

Ç. Çöltekin, SfS / University of Tübingen

largest variance • Find the projection with

• Find the direction of the

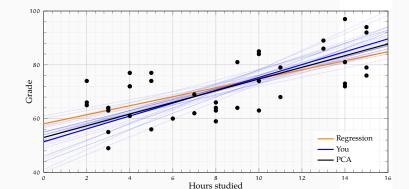

the least reconstruction

• Find a lower dimensional latent Gaussian variable such that the observed variable is a mapping of the latent variable to a higher dimensional space (with added noise)

Recap Clustering Density estimation PCA Autoencoders

 $\hat{\chi}_1$

Recap Clustering Density estimation PCA Autoencoders Aside: your regression estimates and PCA

How to find PCs

- When viewed as maximizing variance or reducing the reconstruction error, we can write the appropriate objective function and find the vectors that minimize it
- In latent variable interpretation, we can use EM as in estimating mixtures of Gaussians
- The principal components are the eigenvectors of the correlation matrix, where large eigenvalues correspond to components with large variation
- A numerically stable way to obtain principal components is doing singular value decomposition (SVD) on the input data

Ç. Çöltekin, SfS / University of Tübingen

Ç. Çöltekin, SfS / University of Tübingen

PCA as matrix factorization (eigenvalue decomposition)

• One can compute PCA by decomposing the covariance matrix as (note $\Sigma = X^T X$)

$$\pmb{\Sigma} = \pmb{U}\pmb{\Lambda}\pmb{U}^T$$

- the columns of **U** are the principal components
- (eigenvectors)
- Λ is a diagonal matrix of eigenvalues
- Another option is SVD, which factorizes the input vector (k variables \times n data points) as

$$X = UDV^*$$

- $\mathbf{U}(\mathbf{k} \times \mathbf{k})$ contains the eigenvectors as before,
- $D(k \times n)$ diagonal matrix $D^2 = \Lambda$
- \mathbf{V}^* is a $\mathbf{n} \times \mathbf{n}$ unitary matrix

* The above is correct for centered variables, otherwise the formulas get slightly more complicated.

Ç. Çöltekin, SfS / University of Tübingen

Recap Clustering Density estimation PCA Autoencoders

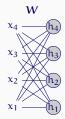

Unsupervised learning in ANNs

- Restricted Boltzmann machines (RBM) similar to the latent variable models (e.g., Gaussian mixtures), consider the representation learned by hidden layers as hidden variables (h), and learn p(x, h) that maximize the probability of the (unlabeled)data
- train a constrained feed-forward network to predict its output

Ç. Çöltekin, SfS / University of Tübingen

Recap Clustering Density estimation PCA Autoencoders

The distribution defined by RBMs

$$p(\mathbf{h}, \mathbf{x}) = \frac{e^{\mathbf{h}^{\mathsf{T}} \mathbf{W} \mathbf{x}}}{\mathsf{Z}}$$

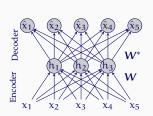

This calculation is intractable (Z is difficult to calculate).

But conditional distributions are easy to

$$\begin{split} p(\mathbf{h}|\mathbf{x}) &= \prod_{j} p(\mathbf{h}_{j}|\mathbf{x}) &= \frac{1}{1 + e^{\mathbf{W}_{j}\mathbf{x}}} \\ p(\mathbf{x}|\mathbf{h}) &= \prod_{k} p(\mathbf{x}_{k}|\mathbf{h}) &= \frac{1}{1 + e^{\mathbf{W}_{k}^{T}\mathbf{h}}} \end{split}$$

Recap Clustering Density estimation PCA Autoencoders

Autoencoders

- Autoencoders are standard feed-forward networks
- The main difference is that they are trained to predict their input (they try to learn the identity function)
- The aim is to learn useful representations of input at the hidden layer
- The weights are often shared/ $\overline{\text{tied}}$ ($W^* = W^T$)

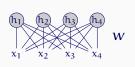

Some practical notes on PCA

- · Variables need to be centered
- Scales of the variables matter, standardizing may be a good idea depending on the units/scales of the individual
- The sign/direction of the principal component (vector) is not important
- If there are more variables than the data points, we can still calculate the principal components, but there will be at most n - 1 PCs
- PCA will be successful if variables are correlated, there are extensions for dealing with nonlinearities (e.g., kernel PCA, ICA, t-SNE)

Ç. Çöltekin, SfS / University of Tübingen

Recap Clustering Density estimation PCA Autoencoders

Restricted Boltzmann machines (RBMs)

- RBMs are unsupervised latent variable models, they learn only from unlabeled data
- They are generative models of the joint probability p(h, x)
- They correspond to undirected graphical models
- No links within layers
- The aim is to learn useful features (h)

*Biases are omitted in the diagrams and the formulas for simplicity.

Ç. Çöltekin, SfS / University of Tübingen

Recap Clustering Density estimation PCA Autoencoders

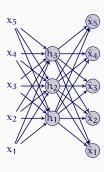

Learning in RBMs

- We want to maximize the probability the model assigns to the input, p(x), or equivalently minimize $-\log p(x)$
- In general, this is computationally expensive
- Contrastive divergence algorithm is a well known algorithm that efficiently finds an approximate solution

Ç. Çöltekin, SfS / University of Tübingen

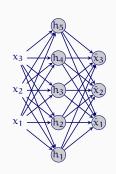

Recap Clustering Density estimation PCA Autoencoders

Under-complete autoencoders

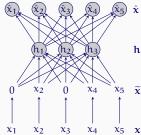

- An autoencoder is said to be under-complete if there are fewer hidden units than inputs
- The network is forced to learn a compact representation of the input (compress)
- An autoencoder with a single hidden layer approximates the PCA
- We need multiple layers for learning non-linear features

Over-complete autoencoders

- · An autoencoder is said to be over-complete if there are more hidden units than inputs
- The network can normally memorize the input perfectly
- This type of networks are useful if trained with a regularization term resulting in sparse hidden units (e.g., L1 regularization)

Denoising autoencoders

- Instead of providing the exact input, we introduce noise by
 - randomly setting some inputs to 0 (dropout)
 - adding random (Gaussian)
- Network is still expected to reconstruct the original input (without noise)

Summary

Recap Clustering Density estimation PCA Autoencoders

Clustering finds groups in the data

• In unsupervised learning, we do not have labels. Our aim is to find/exploit (latent) structure in the data • Unsupervised methods try to discover 'hidden' structure

Density estimation estimates parameters of latent

probability distributions

Dimensionality reduction transforms the data in a low

information in the original data

dimensional space while keeping most of the

Unsupervised pre-training

• A common use case for RBMs and autoencoders are as pre-training methods for supervised networks

Recap Clustering Density estimation PCA Autoencoders

- Autoencoders or RBMs are trained using unlabeled data
- The weights learned during the unsupervised learning is used for initializing the weights of a supervised network
- This approach has been one of the reasons for success of deep networks

Ç. Çöltekin, SfS / University of Tübingen

After the break:

in the data

- Common CL tasks: tokenization, morphology, syntactic parsing, (lexical) semantics,
- Some NLP applications: text classification, and maybe more

Ç. Çöltekin, SfS / University of Tübingen

Derivation of PCA by maximizing the variance

- We focus on the first PC (z_1) , which maximizes the variance of the data onto itself
- We are interested only on the direction, so we choose z_1 to be a unit vector $(||z_1|| = 1)$
- Remember that to project a vector onto another, we simply use dot product, So the projected data points are zxi for
- The variance of the projected data points (that we want to maximize) is,

$$\sigma_{z_1} = \frac{1}{N} \sum_{i}^{N} (z_1 x_i - z_1 \bar{x}_i)^2 = z_1^T \Sigma z$$

where Σ_x is the covariance matrix of the unprojected data

Derivation of PCA by maximizing the variance (cont.)

• The problem becomes maximize

• More ML: sequence learning

$$z_1^{\mathsf{T}}\Sigma_2$$

with the constraint $||z_1|| = z_1^T z_1 = 1$

• Turning it into a unconstrained optimization problem with Lagrange multipliers, we minimize

$$z_1^\mathsf{T} \Sigma z + \lambda_1 (1 - z_1^\mathsf{T} z_1)$$

• Taking the derivative and setting it to 0 gives us

$$\Sigma z_1 = \lambda_1 z_1$$

Note: by definition, z_1 is an eigenvector of Σ , and λ_1 is the corresponding eigenvalue

• z_1 is the first principal component, we can now compute the second principal component with the constraint that it has to be orthogonal to the first one

Ç. Çöltekin, SfS / University of Tübingen
